

QA:

- Only doing analysis, specifying, and validating
- the validating is actually a shared process, its being done by our QC
- For analysis and specifying it is purely done with customer, while validating is a shared process done partly with QC, partly with customer
- **Analysis**
 - We are not looking at the eliciting process, but anything that references any of the process that you are looking at can be part of it, so PS can be looked at
 - Means you need to ensure to have a copy of their PS, or their repo since it references the analysing process
 - Could use interviews/focus groups as a technique to ask the customer for the PS/ their repo (diff techniques can give diff answers to doing the report)
 - QA job is to schedule interviews with the customer, for things that you cannot verify upfront
 - if there's something you want but the customer lost it, ask for declaration sign off to ensure integrity
 - Check that the PS models have been carried forward, cus it should be in their repo. Second is to check if they have revised them, need to show proof. should be able to see both original and revised copies for QA
 - Revision of requirements should have also been done by customer, check for it
 - The customer's IRC should be there and used
 - Use the customer's project scope, to check if they have a plan written for the analysing phase(do they have a checklist? have they done the analysing? what is the end result?)
 - Print out the chat/any other documented evidence from the customer as a proof of their plan prior to their IRC. If you get a ss of the chat as a form of customer evidence, put it in the annex. (annex is a physical copy of some document where the document has to be a standalone external thing; same for declarations. Annex uses numbers, appendices uses letters)
- **Specifying**
 - Requirements you won't be checking whether the requirements are good. you have to know where it came from, so check the repo to make sure the requirements have been brought over
 - For iRTM check whether it is a file or whether it can be converted easily to file, it need to be one page, or at least have pages all in the same annex or appendix
 - Change mitigation: not checking for goodness, could check if they mention they have a template
 - Check if any models were done during specifying, do you see the source document for them like jpg
- **Validating**
 - Sign off after validation: have to ensure that it was signed, if not it's taken as the process is not complete
 - Check whether customer has done grammar checks, spellchecks, editorial checks(duplicated items)

Others:

- Presentation will be 2-3mins (2-4 slides) on findings
- QA report will prolly be shorter than the QC report, they are separate reports but zip them tgt, presentation is compiled together but separate sections
- Slides presentation order: QC first followed by QA
- Main point is to identify what is lacking in the customer's report but not how to fix it
- Come up with a plan for what QA is gonna do (with all other QAs), and come up with a checklist

QC:

- QA to check for QC plans and their checklist(similar to the idea of IRC). Check if they did all the steps and that they saved their findings in their report
- Scenario checking, Persona checking, Assumption checking
- QC is looking for any omissions, QA is checking for the flow of the work
