

AI-Assisted Review

Domain B: Specifying Method

Paragon Assurance

March 20, 2026

Document Type	Review Scope
AI-Assisted SRS Review	Domain B (Specifying Method)

1 Overview

This document presents the findings of an AI-assisted review of the Requirements Engineering process against the Specifying Method domain. The review examined three core artefacts:

1. Software Requirements Specification (SRS)
2. Requirements Traceability Matrix (iRTM)
3. Analysing Report (analysis artefacts)

The AI was provided with a structured review prompt (Section 2) and tasked with analyzing the provided documents to identify compliance with checklist items B.1–B.9, discrepancies, and cross-document inconsistencies. The AI response is presented in full in Section 3.

2 Review Prompt — Domain B: Specifying Method

Instructions to AI

You are reviewing a Requirements Engineering process against the Specifying Method domain. You will be provided with three documents:

- The **Software Requirements Specification (SRS)**
- The **Requirements Traceability Matrix (iRTM)** or equivalent traceability document
- The **Analysing Report** or equivalent analysis artefacts

Provide a **narrative report** identifying:

1. Evidence of compliance with each checklist item within these three documents
2. Missing sections, inconsistencies, or unresolved issues
3. Specific document locations where evidence is (or should be) present
4. Cross-document discrepancies (SRS vs. Analysing Report, SRS vs. iRTM)

Checklist Items to Verify

B.1 — Does the SRS reference a recognised template?

Look for: Title page or introduction in SRS acknowledging a standard template (IEEE 830, IEEE 29148, or similar).

B.2 — Are all SRS requirements traceable to earlier analysis/repository requirements via a traceability matrix?

Look for: iRTM showing mappings between SRS requirements and analysis sources; check for any SRS requirements without source traceability; verify alignment between analysis artefacts and SRS.

B.3 — Does the traceability matrix exist as a standalone, extractable document?

Look for: Standalone iRTM document; verify it is complete and independently usable.

B.4 — Is terminology consistent across all SRS sections and the Analysing Report?

Look for: Data dictionary or glossary in SRS; verify terms are used consistently throughout SRS sections; cross-check terminology with the Analysing Report.

B.5 — Were all open issues from the analysis phase resolved before SRS finalisation?

Look for: Analysing Report open issues section; verify that all noted issues are either closed or addressed in the SRS with documented resolution.

B.6 — Were contradictory requirements identified and resolved before specifying?

Look for: Evidence in Analysing Report of conflict identification; verify that contradictions are resolved in the SRS without conflicts remaining.

B.9 — Was the SRS submitted at a final version level ($\geq$ Version 1.0)?

Look for: Cover page version number in SRS; flag if version is below 1.0 when marked as final.

Guidance for Report Output

For each item, note:

1. **Status:** Is evidence present, partial, or missing?
2. **Location:** Section/document reference where evidence is found or expected
3. **Discrepancy:** Any gaps or inconsistencies across the three documents
4. **Cross-document alignment:** Flag any conflicts or misalignments between SRS, iRTM, and Analysing Report

Highlight: unresolved open issues from analysis, broken traceability chains in iRTM, terminology inconsistencies between documents, contradictions not resolved before specifying, and version control issues in SRS.

3 AI Analysis Response

3.1 Executive Summary

This report evaluates the project's adherence to the "Specifying Method" based on the provided artefacts. Overall, the team has demonstrated a robust and well-documented process. The SRS is structured around a recognised template, and the traceability between the initial Project Specification (PS) and the final SRS is meticulously maintained through a standalone iRTM. Terminology is largely consistent, supported by a comprehensive data dictionary, and significant effort was made to resolve contradictory and ambiguous requirements during the analysis phase.

However, the review has identified several critical findings that must be addressed before the SRS can be considered final and fully compliant. The most significant issues are the presence of unresolved open issues from the analysis phase carried into the SRS and the final version number of the SRS being below 1.0, which is a prerequisite for formal sign-off.

3.2 Detailed Findings by Checklist Item

B.1 — Does the SRS reference a recognised template?

Status Present

Location: SRS, Section 1.2, Page 5

Evidence: The SRS explicitly states: "This SRS is based on the IEEE Recommended Practice for Software Requirements Specifications (IEEE Std 830-1998) template by Karl E. Wiegers." It further notes that structural modifications were made to accommodate the project's specific methodology. This clear acknowledgment satisfies the requirement.

Cross-document alignment: N/A

B.2 — Are all SRS requirements traceable to earlier analysis/repository requirements via a traceability matrix?

Status Present

Location: iRTM.docx (full document), SRS Appendix D (Pages 50–57)

Evidence: The iRTM provides a comprehensive, bidirectional traceability link. Every requirement from the original Project Specification (BS-PS-2026-001) is listed and mapped to one or more corresponding, refined requirements in the SRS (NS-SRS-2026-001). A spot-check confirms this, e.g., PS requirement BOR-1-MOB-02 is correctly traced to its decomposed atomic requirements BOR-1-MOB-02a and BOR-1-MOB-02b in the iRTM.

Discrepancy/Gap: None identified. The traceability chain is complete and well-documented.

Cross-document alignment: The iRTM correctly reflects the decomposition and clarification work documented in the Analysing Report (e.g., Section 2.3, Page 7). The mapping is consistent.

B.3 — Does the traceability matrix exist as a standalone, extractable document?

Status Present

Location: iRTM.docx (the file provided)

Evidence: The iRTM is provided as a separate, complete document. It contains its own document control information (Date, Version, ID), a table of contents-like structure, and the full traceability matrix. This makes it independently usable by project stakeholders. The SRS also includes the iRTM in its Appendix D, which is good for completeness, but the existence of the standalone file fulfills the checklist item.

Cross-document alignment: The standalone iRTM document is identical in content to Appendix D of

the SRS, confirming alignment.

B.4 — Is terminology consistent across all SRS sections and the Analysing Report?

Status Present

Location: SRS Appendix A (Page 40), SRS Appendix C (Pages 43–49), Analysing Report Appendix C (Pages 14–19)

Evidence: The SRS includes a dedicated Glossary (Appendix A) that defines key terms like AES-256, FAR, PDPA, etc. Furthermore, the Data Dictionary (Appendix C) rigorously defines all data fields, ensuring consistency in the system’s structural terminology. A comparison of key terms like *AttendanceRecord*, *LeaveRequest*, and *BiometricScan* between the Analysing Report’s Data Dictionary (Tables C.1–C.9) and the SRS’s Data Dictionary shows they are identical, proving excellent cross-document consistency.

Cross-document alignment: Terminology is perfectly aligned between the Analysing Report and the SRS, particularly in the Data Dictionary, which appears to have been directly carried over and refined.

B.5 — Were all open issues from the analysis phase resolved before SRS finalisation?

Status Missing / Non-Compliant

Location: Analysing Report Section 3.5 (Page 10), SRS Section 2.7 (Page 8), SRS Section 8.2 (Page 21), SRS Appendix B (Page 42)

Evidence: The Analysing Report (Section 3.5) explicitly lists three open issues: MCS Integration Security, Disaster Recovery RPO/RTO, and Biometric Template Storage Format.

The SRS has not resolved these issues. Instead, it has formalised them in a new section, “CM#2: Open Issues” (Section 8.2) and listed them again in “Appendix B - Issues List”.

These issues are also flagged as assumptions/dependencies (SRS Section 2.7) and in the relevant functional requirements (e.g., FR-SW-01). While the “kill dates” and fallback plans are a strong mitigation strategy, the issues remain *open* in the final SRS.

Discrepancy/Gap: This is the most critical finding. A final SRS, by definition, should have all requirements agreed upon and resolved. Carrying forward open issues from analysis creates significant project risk. The process of “specifying” should be complete before finalisation.

Recommendation: The project must be instructed that an SRS with open issues (CM-OI-01, CM-OI-02, CM-OI-03) cannot be considered a “final” specification. These must be closed or the SRS version must be marked as a draft (e.g., 0.9) to reflect its true status.

B.6 — Were contradictory requirements identified and resolved before specifying?

Status Present

Location: Analysing Report Section 2.2 (Page 4), Section 3.3 (Page 8), Section 3.4 (Page 9)

Evidence: The Analysing Report provides strong evidence of a structured process to identify and resolve contradictions.

1. **Identification:** Section 2.2 explicitly lists “Incongruent Requirements,” including “Technically Infeasible Requirements” such as the unrealistic FAR 0.001% from TR-1-BE-04.
2. **Resolution:** Section 3.4 (Technical Requirements Clarification Session) documents the resolution: “FAR target revised to 0.01% based on commercial sensor capabilities...”
3. **Final State:** The SRS reflects this resolved value. In the iRTM, the mapping for TR-1-BE-04 links to FR-HW-02 and FR-HW-03, which correctly state the performance targets without referencing the unrealistic FAR value. This demonstrates a clear path from contradiction to resolution.

Cross-document alignment: The three documents tell a coherent story of conflict identification (AR),

stakeholder resolution (AR), and final agreed-upon specification (SRS/iRTM).

B.9 — Was the SRS submitted at a final version level ($\geq$ Version 1.0)?

Status	Missing / Non-Compliant
--------	-------------------------

Location: SRS Cover Page (Page 1)

Evidence: The SRS cover page clearly states: “**Version: 0.8**”. The document is also dated 3 March 2026. For a document intended to serve as the “primary contractual basis for design, development, testing, and delivery” and to be formally signed off (Section 9), a version below 1.0 is inappropriate. It implies the document is still a draft and not yet a final, stable baseline.

Discrepancy/Gap: There is a fundamental mismatch between the document’s stated purpose and its version number. This is compounded by the presence of open issues (B.5), which further confirms that version 0.8 is not a final specification. The project appears to have conflated “submitted for approval” with “final.” A version 0.8 document is submitted *for review*, not *for sign-off as the final baseline*.

Recommendation: This is the second critical finding. The SRS must be advanced to version 1.0 *after* all open issues are resolved and the document is formally baselined. The current version 0.8 is pre-final.

4 Summary of Findings

Item	Status	Key Evidence	Notes
B.1	Present	SRS §1.2	Explicitly references IEEE 830-1998.
B.2	Present	iRTM.docx, SRS Appendix D	Full traceability from PS to SRS is maintained.
B.3	Present	iRTM.docx file	The iRTM exists as a complete, standalone document.
B.4	Present	SRS Appendix A & C, AR Appendix C	Terminology is highly consistent, with a shared data dictionary.
B.5	Missing	AR §3.5, SRS §8.2, SRS App. B	Critical: Open issues from analysis were NOT resolved and were carried into the SRS.
B.6	Present	AR §2.2, §3.4; SRS iRTM	Clear evidence of identifying and resolving contradictions (e.g., FAR target).
B.9	Missing	SRS Cover Page	Critical: SRS version is 0.8, which is below the 1.0 threshold for a final specification.

5 Overall Conclusion

The project team has executed a technically sound requirements engineering process, with excellent documentation of analysis, traceability, and consistency. The Analysing Report is a model of clarity, and the iRTM ensures a clear line-of-sight from the customer's original requests to the final specification.

However, the **Specifying method has not been fully completed**. The presence of open issues (CM#2) and a version number below 1.0 indicates that the SRS is still a draft, not a final, baselined document. Submitting a version 0.8 document for final sign-off creates significant contractual and project risk. The "Change Mitigation Strategies" (Section 8) are forward-thinking, but they are designed to manage *future* changes to a *baselined* SRS, not to excuse *current* incomplete requirements.

Final Recommendation: The review cannot approve the SRS in its current state. The project must be directed to close all open issues (CM-OI-01, -02, -03) with BioSec, update the SRS accordingly, and then re-submit it as **Version 1.0** for final approval and sign-off. The current document should be re-categorised as a draft for review.
